1 Purpose

The goal is to get you writing more interesting algorithms and using more interesting data types.

2 Getting it

Download the project ZIP file to your computer\(^1\), unzip it, and open the resulting directory in CLion. (Be careful that you open the hw06 directory and not some sub- or superdirectory thereof. If you do, CLion

\(^1\)To complete this homework on your own computer, you need a C++14 toolchain and the SDL2 libraries. Follow these instructions to install them on your own computer, or if you need to work on a lab computer instead then see here.
will create a bogus CMakeLists.txt that won’t be able to find SDL2.)

3 Specification

The game Reversi is played by two players, Dark and Light, laying dark- and light-colored tiles on an 8-by-8 board. The game proceeds in two phases.

In the opening phase, the players alternate turns, placing tiles in the center four squares of the board ((3, 3), (3, 4), (4, 3), and (4, 4) if 0-based). Dark goes first, and the opening phase ends when the center four squares are occupied.

In the main phase, each move must capture at least one of the other player’s tiles, as follows. The current player places a tile in an unoccupied square so that it forms at least one straight line—horizontal, vertical, or diagonal—with one or more of the other player’s tiles in the middle and one of the current player’s tiles on the other end. Then the other player’s tiles in the line(s) are flipped to the current player. (See figure 1 for some example moves.)

The players take turns unless one player cannot play, in which case the other player may play again. The game is over when neither player can play. The winner is the player with more tiles on the final board (or it may be a tie).

3.1 Generalization to smaller sizes

To facilitate testing, we generalize the rules of Reversi to allow boards with dimensions down to 2-by-2, including non-square boards (e.g., 7-by-4). To generalize the opening phase of the game to a w-by-h board, we define the center four squares to be at positions \((c_x - 1, c_y - 1)\), \((c_x - 1, c_y)\), \((c_x, c_y - 1)\), and \((c_x, c_y)\), where \(c_x = \lfloor w/2 \rfloor\) and \(c_y = \lfloor h/2 \rfloor\).

For your convenience, a rectangle containing these positions (which you can iterate over) is returned by `Board::center_positions()` const.

3.2 Your implementation

To start the game, the user runs the `reversi` executable with either no command-line arguments, or two arguments, the width and height of the board. If the width or height are out of range, or if some other number of arguments is given, then the program exits with an error message.

The user interface must make it possible to play the game using either the mouse or the keyboard (or both, if you wish). The game must allow the user to make all legal moves and no illegal moves. It must display the state of the model so that the user can see which squares are occupied by light tiles, which by dark tiles, and which by neither. When the game is not over, it should display whose turn it is and give some indication of which squares are valid to play in. For full credit, it should also give feedback on which tiles will flip as a result of each possible move. When the game ends, the UI must indicate which player, if any, has won.

It should not be possible for the user to cause the game to crash via any interaction with the UI.
4 Helper type reference

To help define the model, we have provided several types to build upon. We present these types in this section before discussing the model itself in section 5.1 on page 5. The helper types are:

- A Position_set represents a set of game board positions. (See section 4.1.)

- Type Move represents a possible move as a pair of a single ge211::Position in which a player can place a tile, and the Position_set of all positions gained by that move. (See section 4.2 on the next page.)

- Type Move_map holds a collection of available Moves whose first components are distinct, and which supports looking up Moves by their first components. (This is the type of the next_moves_ member variable of the Model class that your operations need to maintain.) (See section 4.2 on the following page.)

- Player is an enum class with three enumerators: dark, light, and neither. (See section 4.3 on the next page.)

- Class Board represents the state of the board. (See section 4.4 on the following page.)

4.1 The Position_set class

The Position_set class is used to represent a set of positions and offers a standard selection of set operations. Position_sets support equality and stream insertion (printing), which may be helpful for testing and debugging.

The full documentation may be found in the src/move.hxx header, but the highlights are described here.

```cpp
bool Position_set::empty() const;
```

Returns whether this set is empty.

```cpp
void Position_set::clear();
```

Removes all elements from this Position_set.

```cpp
bool Position_set::operator[](Position) const;
```

Looks up the given position in the set, returning a bool indicating whether it is present.

```cpp
Position_set::reference Position_set::operator[](Position);
```

Looks up the given position in the set, returning a reference-like object that can be assigned a bool to change whether the position is in the set. For example:

```cpp
Position_set pset;
// add {2, 3} to `pset`:
pset[{2, 3}] = true;
// remove {2, 3} from `pset`:
pset[{2, 3}] = false;
```

```cpp
Position_set& Position_set::operator|=(Position_set);
```

Adds the positions in the given set to this set. Additionally, Position_set supports the full complement of set operations:

- intersection: a & b and a &!= b
- union: a | b and a |!= b
- symmetric difference: a ^ b and a ^= b
- complement: ~a

Note that set difference can be accomplished with intersection and complement: a & ~b.

---

2 It is limited to positions whose coordinates are both less than 8, which suffices for Reversi.
4 Helper type reference

Position_set::iterator
Position_set::begin() const;
Position_set::iterator
Position_set::end() const;

These functions return the iterators necessary to iterate over a Position_set using a range-based for loop, like so:

```cpp
for (ge211::Position pos : pset) {
    ...
}
```

4.2 Type aliases Move and Move_map

```cpp
struct Move {
    ge211::Position first;
    Position_set second;
};
```

The Move type (see src/move.hxx) is an instantiation of the standard library's std::pair template struct. It has two member variables, first and second. The former contains the position of the move, and the latter is the set of all positions gained by the move, including both the move itself and any flips.

Moves support equality and stream insertion (printing), which may be helpful for testing and debugging.

```cpp
using Move_map = std::unordered_map<
    ge211::Position,
    Position_set
>;
```

Type Move_map (also in src/move.hxx) is an instantiation of the standard library's std::unordered_map with ge211::Position as the key type and Position_set as the value type. Move_maps support equality but not stream insertion.

All the std::unordered_map operations are available, but you will mostly likely need only these three:

```cpp
Position_set&
Move_map::operator[](
    ge211::Position);
```

Type Move_map overloads the indexing operator (square brackets) to take a ge211::Position. If the position is not already present then it inserts the given position paired with an empty Position_set. It then returns a reference to the Position_set, which allows the caller to modify or assign it. Thus, we can associate a position pos with a set of positions pset by indexing the move map with pos and assigning pset to the result:

```cpp
mmap[pos] = pset;
```

```cpp
bool Move_map::empty() const;
```

Returns whether this move map is empty, meaning no positions have been mapped to position sets.

```cpp
void Move_map::clear();
```

Removes all moves from this move map.

4.3 The Player enumeration

There are three Player values: Player::dark and Player::light represent the two players, and Player::neither represents absence of a player. Players support equality and stream insertion (printing), which may be helpful for testing and debugging.

There is one operation you will need:

```cpp
Player other_player(Player);
```

Returns the other player.

4.4 The Board class

The Board class stores the state of the Reversi board. It is, essentially, an updatable mapping from in-bounds ge211::Positions to Players. Boards support equality and stream insertion (printing), which may be helpful for testing and debugging.

The full documentation of the Board class is available in the src/board.hxx header file, but the highlights you are likely to want are described here.

```cpp
ge211::Dimensions
Board::dimensions() const;
```

Returns the dimensions of the board.

```cpp
Player
Board::operator[](ge211::Position)
const;
```

Returns the player at the given position.
5 Design orientation

Returns a reference-like object that, when a Player is assigned to it, stores that Player in the board at the given position. For example, this statement stores Player::dark at board position (2, 3):

```cpp
board[{2, 3}] = Player::dark;
```

Stores the given Player in the board at all the positions in the given Position_set. For example, these statements store Player::light at two board positions:

```cpp
Position_set pset{{2, 5}, {3, 4}};
board.set_all(pset, Player::light);
```

Returns the number of times the given player appears on the board.

Returns a rectangle containing all of the board’s positions. Since ge211::Rectangles are iterable, this can be used to iterate over the board’s positions:

```cpp
for (ge211::Position pos : board.all_positions())
...
```

Returns a rectangle containing just the four center positions that are playable in the opening phase. Since ge211::Rectangles are iterable, this can be used to iterate over the four center positions:

```cpp
for (ge211::Position pos : board.center_positions())
...
```

5 Design orientation

In this section we describe the design of the three classes that you have to complete.

5.1 The model

The Model class (src/model.{hxx,cxx}) encapsulates the state of the game and its rules. In particular, it keeps track of:

- the current turn, if the game is ongoing (Player turn_),
- the winning player, if any (Player winner_),
- the state of the board (Board board_), and
- a cache of which moves are available to the current player (Move_map next_moves_).

While it is possible to generate the available moves on demand given the other three data members, this information is not cheap to compute, and the view and controller will most likely need it much more often than it changes. So it makes sense to compute the next possible moves when the game starts and then after each turn, rather than recomputing it whenever the UI wants to know which moves are valid.

In the Model class, we have defined a number of member functions that you may want to call from the view, the controller, or elsewhere in the model:

- Model::board() const returns a ge211::Rectangle that contains all positions in the board.
- Model::is_game_over() const returns a bool indicating whether the game is over.
- Model::turn() const returns the current player, if any.
- Model::winner() const returns the winning player, if any.
5 Design orientation

- Model::operator[](ge211::Position) const returns the Player at the given position on the board.
- Model::find_move(ge211::Position) const returns a pointer to the Move that would result from playing at the given position, if allowed, or nullptr if not allowed.

The last of these depends on the contents of next_moves_ being correct. Ensuring that invariant is your job. In particular, there are two members of the Model class that are incomplete:

```cpp
void Model::play_move(ge211::Position);
```

This function plays a move at the given position if allowed, or throws an exception if disallowed. We have already provided code to check the legality of the move for you and throw if necessary. Our starter code leaves a pointer to the valid Move in a local variable, movep. Your responsibility is to 1) actually execute the move by modifying the board, or change the other player if they can move, or back to the same player if the other player cannot move, or to game over if neither player can move, and 3) leave next_moves_ in a correct state.

```cpp
Model::Model(int width, int height);
```

This constructor initializes the model. We’ve provided you the member initializer for the board, but you need to write the code for filling next_moves_ with the moves available to the first player on the first turn. (This should probably happen via a private helper function that Model::play_move calls as well.)

5.2 The view

The responsibility of the View class is to present the state of the model in such a way that users can play the game. We have not specified what the game should look like, other than that it must be playable as described in section 3.2 on page 2. You may emulate the style of the diagrams in figure 1 on page 2 if you wish, or design something else.

We have provided you with a minimal View class in src/view.{hxx,cxx}, which you will have to complete to make the game playable. This starter View class defines a single member variable, Model const& model_. It defines one constructor, which initializes model_; you may want to extend this constructor to initialize your sprites as well. Two member functions, for determining the window title and dimensions, are provided for you (though you may change them if you want to determine these things differently).

There is one function for you to write: View::draw(ge211::Sprite_set&). This function is, of course, responsible for determining what appears on the screen. You will most likely want to add at least one parameter to it, so that the controller can communicate control state (such as the position of the mouse) to the view.

5.3 The controller

The responsibility of the Controller class is to receive input from the user and decide what to do with it. We have not specified how control should work, other than that the game must be playable as described in section 3.2 on page 2. You may provide mouse control, keyboard control, or whatever usable interface you desire.

We have provided you with a minimal Controller class in src/controller.{hxx,cxx}, which you will have to complete to make the game playable. This starter Controller class defines two member variables to hold the model and the view. It defines two constructors, each of which allows specifying the model dimensions, and initializes the model and the view. We have also overridden member functions draw, initial_window_dimensions, and initial_window_title in order to delegate those three responsibilities to the view.

You will need to add user-input handling to the controller by overriding additional member functions of ge211::Abstract_game, such as:

- on_mouse_down if you want to react to mouse clicks,
- on_mouse_move if you want to react to mouse motion, and
- on_key if you want to react to typing on the keyboard.

You will probably want to add at least one private member variable to the Controller class to keep track of the UI state. For example, if you want the view to indicate the current player’s available moves and their consequences based on where the mouse is pointing, then the controller needs to store the mouse position on each call to on_mouse_move so that it can then pass it to the view when it calls View::draw from Controller::draw.
6 Implementation hints

This section provides supplementary material to help you figure out how to implement the specification.

6.1 Model factoring

Your main responsibility with respect to the model implementation is to handle playing moves, and the most difficult part of that is computing the available moves to update next_moves_. In src/model.hxx we have declared six suggested private helper functions to help you break down this task. You don’t need to use them or even implement them, but you may find them useful. The suggested private helpers are:

- **find_flips_(Position, Dimensions) const** takes the position of a prospective move by the current player and a direction to search in (as provided by Board::all_directions()). It searches for a straight line of opposing player tiles bounded by the given position at one end and an existing tile belonging to the current player on the other end. It returns the set of those opposing player positions (which will be empty if there is no such line).

  This is a helper for...

- **evaluate_position_(Position) const** takes the position of a prospective move and returns a Position_set containing all positions that would be gained by the current player playing in that position, if allowed (or the empty set if playing in the given position is disallowed).

  This is a helper for...

- **compute_next_moves_()** clears out next_moves_ and then regenerates it with all moves currently available to the current player.

  This is a helper for the Model(int, int) constructor and for...

- **bool advance_turn_()** switches the turn to the other player, regenerates next_moves_, and then returns whether any moves are actually available to the new current player.

  This is a helper for really_play_move_ (below).

- **void set_game_over_()** makes the game over by setting the current player to Player::neither and storing the winner, if any, in winner_.

  This is also a helper for...

- **void really_play_move_(Move)** executes the given move by setting the appropriate positions on the board and then advancing the turn or setting game over. It needs to try advancing the turn twice—since if the other player cannot play then the current player gets to play again. Only if neither player has any moves available is the game over.

6.2 Algorithm for computing moves

Computing next_moves_ requires a somewhat involved algorithm, since it must evaluate every unoccupied board position, or sometimes just four (compute_next_moves_); and to evaluate each position (evaluate_position_), it must check for “flippable lines” of opposing player tiles in all eight directions (find_flips_).

Finding one line of flips

Given a starting, unoccupied position start and a direction dir to search in, we can find a line of flippable positions as follows. Start with an empty Position_set to hold the result, and begin checking positions moving away from start: start + dir, start + 2 * dir, and so on. At each position there are three possibilities:

- If we reach a position that would go off the board (check that first!) or is unoccupied then there is no flippable line to find, so the result is the empty set.

- If a position contains an opposing player tile then we add that position to our result Position_set and move on to the next.

- If we reach a position containing the current player’s tile then we return the Position_set that we’ve accumulated.

Evaluating a position

We evaluate a position pos as the set of all positions that the current player would gain by playing there—or the empty Position_set if playing there is not allowed. First we check if it’s unoccupied, since occupied positions are not playable and evaluate to the empty set. Otherwise, we need to search for flippable lines in all eight directions starting from pos (probably by iterating over the result of Board::all_directions()), and union together the eight resulting Position_sets. (You can do this by starting with an empty Position_set and then using the |= operator to union each result of find_flips_...
6 Implementation hints

Evaluating the whole board (as necessary)

Evaluating the whole board means first clearing next_moves_, then checking for available moves and adding them to next_moves_.

Before evaluating every board position, we need to check whether any of the four center positions (board_.center_positions()) are unoccupied, which would indicate that we are still in the opening phase of the game. Since playing in one of those positions would not flip any other tiles, each unoccupied center position gets mapped to the singleton set of itself:

\[
\text{next_moves_[pos]} = \{ \text{pos} \};
\]

If, after adding any unoccupied center positions, next_moves_ is non-empty, then we are still in the opening phase and should return next_moves_ without checking the rest of the board.

Otherwise we are in the main phase, so we must evaluate each position in the board and record each non-empty evaluation in next_moves_. In particular, if some position pos is a legal move that evaluates to some Position_set pset then we store this fact in next_moves_ like so:

\[
\text{next_moves_[pos]} = \text{pset};
\]

Positions that evaluate to the empty set must not be added to next_moves_, as that would cause play_move to consider them to be available moves.

6.3 The UI

The UI description in section 3.2 on page 2 imposes a number of requirements on what the player can do. You are free to implement these requirements however you like, but here is a list of suggestions for how you could:

- Display the board as a grid of squares, with the Dark and Light players' tiles as slightly smaller black and white circles placed over them. (To place one sprite atop another, you need to provide different z values as a third argument to Sprite_set::add_sprite.)
- Once the game is over, indicate the winner by rendering all non-winning tiles in gray instead of black or white.
- Indicate the current turn (when the game isn’t over) by having an image of the current player’s tile (or something similar?) follow the mouse pointer.

(This requires adding the mouse position as a private member variable in the Controller class.)

- When the mouse points to a square in which the current player is allowed to move, indicate the effect of moving in that position by changing the color of the squares in the positions that would be gained by the player. The view can easily discover this information by calling Model::find_move with the logical (board) position of the square that the mouse pointer currently points to.

(This also requires adding the mouse position as a private member variable in the Controller class.)

You may find some helper functions useful. For example, my View class includes these three:

```cpp
ge211::Position
View::board_to_screen(  
    ge211::Position) const;

ge211::Position
View::screen_to_board(  
    ge211::Position) const;

void
View::add_player_(  
    ge211::Sprite_set&,  
    Player,  
    ge211::Position,  
    int z) const;
```

The first two convert positions from logical to physical and back. The third one adds the tile sprite for the given player at the given physical position and z layer, while ignoring Player::neither and turning non-winning players' tiles gray if the game is over.

6.4 Testing private members

Given that the model’s move evaluation algorithm involves several steps and nested loops, how can you test some smaller portions of it? Well, the first step is factoring it into smaller, more testable pieces, such
6 Implementation hints

as the suggested helper functions. But these are private, which means that your tests won’t be able to access them, right?

Not exactly. We declared a friend struct Test_access in the Model class, which means that Model grants, to any members of a struct called Test_access, access to its own private members. This is there for the grading tests, but you can define a Test_access struct in order to provide your tests with privileged access to the model as well.

For example, if you wanted your tests to be able to access the board directly and to call the private find_flips_ helper, you might write this:

```cpp
struct Test_access
{
    Model & m_; 
    Board & board()
    {
        return m_.board_; 
    }
    Position_set
    find_flips(Position start, Dimensions dir)
    {
        return m_.find_flips_(start, dir); 
    }
};
```

Then you could use it like this:

```cpp
TEST_CASE("simple flips case")
{
    Model model;
    Test_access t{model};
    t.board()[{2, 2}] = Player::dark;
    t.board()[{2, 3}] = Player::light;
    Position_set f;
    f = t.find_flips({2, 4}, {0, 1});
    CHECK(f.empty());
    f = t.find_flips({2, 4}, {0, -1});
    CHECK(f == Position_set{{2, 3}});
}
```

6.5 Which files should I change? Which files may I change?

It may be difficult figuring out what is necessary to change, what is safe to change, and what will cause trouble with grading. This section divides all the provided starter code files into categories based on how you should change them.

- One file you definitely must change, but carefully:
  - `src/model.cxx` – in particular:
    - Do fill in the sections marked TODO in the Model(int, int) constructor and play_move member function,
    - Do define any private helper functions you like, including those we suggest and/or your own ideas, but
    - Don't modify any of the existing, complete function implementations.

- Five files you definitely must change, and may change however you like:
  - `src/view.{hxx,cxx}
  - `src/controller.{hxx,cxx}
  - `test/model_test.cxx

- Six files you must not change:
  - `src/move.{hxx,cxx}
  - `src/player.{hxx,cxx}
  - `src/board.{hxx,cxx}

- Three files you may change at your discretion, but carefully:
  - `src/model.hxx` – in particular:
    - Do add any private members (most likely helper functions) you want, but
    - Don't alter the declarations of any public members, and
    - Don't alter the definitions of private member variables turn_, winner_, board_, and next_moves_.
  - `src/reversi.cxx` – unlikely, but:
    - Don't change how command-line arguments are handled, but
    - Do change anything else, as you like.
  - `CMakeLists.txt` – unlikely, but:
    - Do add any new model .cxx files you create to the variable MODEL_SRC, but
    - Don't change anything else.

- Three files you may change, but probably don’t have reason to:
  - `test/{board,move,player}_test.cxx`
7 Deliverables and evaluation

For this homework you must:

1. Complete the two partially-implemented `Model` members (the two-argument constructor and function `play_move`) in `src/model.cxx`.

2. Complete the design and implementation of the `View` and `Controller` classes in `src/{view,controller}.{hxx,cxx}`, so that the game is playable.

3. Add more test cases to `test/model_test.cxx` in order to test that the model functions properly.

   (We don’t have a way for you to write automated tests for the UI, but you should test it interactively.)

As usual, self evaluation will spot-check your test coverage by asking for just a few particular test cases. You can’t anticipate what cases we may ask about, so you should try to cover everything.

Your grade will be based on:

- the correctness of your `Model` implementation with respect to the specification,
- the playability of your UI,
- the presence of sufficient test cases to ensure your model code’s correctness, and
- adherence to the CS 211 Style Manual.

8 Submission

Homework submission and grading will use the GSC grading server. You must include any files that you create or change. For this homework, that will definitely include `src/model.cxx`, `src/view.hxx`, `src/view.cxx`, `src/controller.hxx`, `src/controller.cxx`, and `test/model_test.cxx`. See section 6.5 on the previous page for a comprehensive list of which files you must and may change.

You should upload your files on the GSC web site.3

8.1 Partners

If you work with a partner then you must register your partnership before uploading to GSC. There are two steps to this: one partner must create a partner request (referring to their intended partner by NetID), and then the other partner must accept that request for it to take effect.

Create partner requests on the GSC website or using the command-line tool; outstanding partner requests will appear on the page for the relevant homework as well as your main GSC submissions page.

Before a partner request can be accepted, the files in the two submissions must be disjoint. (The system will not choose whose file to delete if you both have files with the same name.) Once a partner request is accepted, you and your partner’s submissions are joined together: when one partner uploads files to the GSC server or performs self evaluation, the results will be visible to both.

---

3It’s also possible to install the command-line GSC client `gsc(1)` on your local machine.

4Be careful with partner registration, because once a partner request is accepted, undoing it requires an appeal to the instructor.
