Before we start

• Host to use for your assignments:
  hanlon.wot.eecs.northwestern.edu
  • Login to it (ssh YOUR_NET_ID@hanlon.wot.eecs.northwestern.edu)
  • Run “bash”
  • Run “source /opt/rh/devtoolset-8/enable”
  • Suggestion: use .bashrc to do it automatically

• Pair programming
  • If you want to do it, then send to the TA an email to declare your pair
    before the next lecture
  • After this deadline, you can only split (no new pairs are allowed)
Homework

• Compiler assignment
  • Day X: you have the assignment
  • Deadline: before the same day of the next week
  • Your compiler has to pass all tests included in the framework

• Program assignment (when I’ll mention in the class)
  • You need to write Y programs
    in the source language of that assignment
  • Deadline: 2 days

• Late assignment: you cannot be selected as a panelist
Compilers

• Compilers translate a source language (e.g., C++) to a destination language (e.g., x86_64)
  • We use them every day
  • If you understand their internals, you better understand (and take advantage of) the tools you rely on
  • Are you interested in computer architectures? Their inputs is the outputs of a compiler
Outline

• Assembler, linker
• L1 language
• Value encoding
• Calling convention
• Heap
Assembler

- Translate assembly instructions (e.g., movq $5, %rdi) to their machine code representation (e.g., 48 c7 c7 05 00 00 00)
- Replace labels (e.g., jmp _cool...

    _cool:
    OTHERS

) to actual offsets (e.g., jmp 42...

    OTHERS

)
- Embed machine code instructions in an object file (e.g., ELF)
  
  $ gcc -c yourfile.c -o yourfile.o
  $ file yourfile.o
  yourfile.o: ELF 64-bit LSB relocatable, x86-64 ...

Executable and Linkable Format

Linux Standard Base
Assembler in action

```assembly
.Go:
  movq $2, %rdi
  inc %rdi
  call print
  ret
```

```
mov $0x2,%rdi
inc %rdi
callq 29 <0xf>
retq
```

```
48 c7 c7 02 00 00 00
48 ff c7
e8 00 00 00 00
c3
```

```
 prog.S
```

```
 prog.o
```
Linker

- Link object files together and link them with existing libraries (e.g., libc)
- `callq 29 <0xf>`

- Relative offsets can now become absolute
- Undefined symbols (e.g., print) are now resolved
Putting it all together

• Let’s say we have assembly instructions in prog.S
• Let’s say we have a runtime in runtime.o
• To invoke the assembler:
  $ as –o prog.o prog.S
• To invoke the linker
  $ gcc –o a.out prog.o runtime.o
• How to actually invoke the linker (ld) requires platform-specific information
  • gcc invokes the linker for your platform (hanlon)
  • You want to know how? Run “gcc –v –o a.out prog.o runtime.o”
Outline

• Assembler, linker

• L1 language

• Value encoding

• Calling convention

• Heap
The L1 source language

• Similar to a subset of x86_64, but with some abstractions
  \[ \text{movq } $1, %\text{rax} \rightarrow \text{rax } <- 1 \]

• L1 is going to be the input of your first compiler L1c

• The output of L1c is an executable ELF binary
  • You will rely on the GNU assembler and linker

L1 program \(\rightarrow\) Your work \(\rightarrow\) prog.S \(\rightarrow\) as, ld \(\rightarrow\) a.out
L1 program

\[ p ::= (\text{label } f^+) \]

\textit{label ::= sequence of chars matching} :\[a-zA-Z_][a-zA-Z_0-9]^*\]

(\textbf{:go} \leftarrow \text{The entry point of this L1 program is the function} :\textbf{go})

\textbf{f1} \leftarrow \text{One of these functions must be :go}

\textbf{f2} \leftarrow
L1 function

\[ p ::= ( \text{label } f^+) \]

\[ \text{label ::= sequence of chars matching } [a-zA-Z] [a-zA-Z_0-9]^* \]

\[ f ::= ( \text{label } N N i^+) \]

\[ N ::= (+|-)? [1-9][0-9]^* \]

\[ (:go \ 4 \ 2 \ i1 \ i2 \ ) \]
L1 instruction: assignment

\( p \ ::= (\text{label } f) \)

\( \text{label} ::= \text{sequence of chars matching} :[a-zA-Z_][a-zA-Z_0-9]^* \)

\( f ::= (\text{label } N N \text{ i}) \)

\( i ::= w \Leftarrow s \)

\( w ::= a | rax | rbx | rbp | r10 | r11 | r12 | r13 | r14 | r15 \)

\( a ::= \text{rdi} | \text{rsi} | \text{rdx} | \text{rcx} | r8 | r9 \)

\( s ::= x | N | \text{label} \)

\( x ::= w | \text{rsp} \)
L1 example

(:go
  (:go
    4 2
    rdi <- 5
    rax <- rdi
  )
)
L1 instruction: load

\[
p ::= (\text{label } f^+) \\
\text{label} ::= \text{sequence of chars matching } [a-zA-Z_] [a-zA-Z_0-9]^* \\
f ::= (\text{label } N N i^+) \\
i ::= w <- s \mid w <- \text{mem } x \text{ M} \\
w ::= a \mid \text{rax} \mid \text{rbx} \mid \text{rbp} \mid \text{r10} \mid \text{r11} \mid \text{r12} \mid \text{r13} \mid \text{r14} \mid \text{r15} \\
a ::= \text{rdi} \mid \text{rsi} \mid \text{rdx} \mid \text{rcx} \mid \text{r8} \mid \text{r9} \\
s ::= x \mid N \mid \text{label} \\
x ::= w \mid \text{rsp} \\
M ::= N \text{ times 8 (e.g., 0, 8, 16)}
\]
L1 example

(:go
  (:go
    4 2
    rdi <- 5
    rax <- rdi
    rbx <- mem rdi 8
  )
)
)
L1 instruction: load

\[p ::= \text{(label } f^+)\]

\text{label ::= sequence of chars matching :}[a-zA-Z_][a-zA-Z0-9]*\]

\[f ::= \text{(label } N N i^+)\]

\[i ::= w <- s | w <- \text{mem } x \ M\]

\[w ::= a | \text{rax} | \text{rbx} | \text{rbp} | r10 | r11 | r12 | r13 | r14 | r15\]

\[a ::= \text{rdi} | \text{rsi} | \text{rdx} | \text{rcx} | r8 | r9\]

\[s ::= x | N | \text{label}\]

\[x ::= w | \text{rsp}\]

\[M ::= N \text{ times 8 (e.g., 0, 8, 16)}\]
L1 instruction: store

\[ p ::= (\text{label } f^+) \]

\text{label ::= sequence of chars matching :}[a-zA-Z_][a-zA-Z0-9]*\]

\[ f ::= (\text{label } N N i^+) \]

\[ i ::= w <- s \mid w <- \text{mem } x \ M \mid \text{mem } x \ M <- s \]

\[ w ::= a \mid \text{rax} \mid \text{rbx} \mid \text{rbp} \mid r10 \mid r11 \mid r12 \mid r13 \mid r14 \mid r15 \]

\[ a ::= \text{rdi} \mid \text{rsi} \mid \text{rdx} \mid \text{rcx} \mid r8 \mid r9 \]

\[ s ::= x \mid N \mid \text{label} \]

\[ x ::= w \mid \text{rsp} \]

\[ M ::= N \times 8 \text{ (e.g., 0, 8, 16)} \]
L1 instruction: arithmetic operations

\[ p ::= (\text{label } f^+) \]

\[ \text{label} ::= \text{sequence of chars matching } [a-zA-Z_][a-zA-Z_0-9]^* \]

\[ f ::= (\text{label } N N \text{ i}^+) \]

\[ i ::= w < - s \mid w < - \text{mem x M} \mid \text{mem x M} < - s \]
\[ \mid w \text{ aop } t \]

\[ \text{aop} ::= += \mid -= \mid *= \mid &= \]

\[ t ::= x \mid N \]
L1 example

(:go
 (:go
   4 2
   rdi <- 5
   rdi += 2
 )
)
)
L1 instruction: arithmetic operations

\[
p \ ::= \ (\text{label } f^+) \\
\text{label} \ ::= \text{sequence of chars matching } :[a-zA-Z_][a-zA-Z_0-9]^* \\
f \ ::= \ (\text{label } N N i^+) \\
i \ ::= \ w \leftarrow s \mid w \leftarrow \text{mem x M} \mid \text{mem x M} \leftarrow s \\
\mid w \ \text{aop t} \\
aop \ ::= \ +\mid -\mid *=\mid &= \\
t \ ::= \ x \mid N
\]
L1 instruction: shifting

\[ p \ ::= (\text{label } f^+) \]
\[ \text{label} ::= \text{sequence of chars matching } :[a-zA-Z_][a-zA-Z_0-9]^* \]
\[ f ::= (\text{label } N N i^+) \]
\[ i ::= w \gets s \mid w \gets \text{mem } x \ M \mid \text{mem } x \ M \gets s \]
\[ \quad \mid w \text{ aop } t \mid w \text{ sop } rcx \]
\[ \text{sop} ::= \lll \mid \llll \]
L1 instruction: shifting

\[ p ::= (label \ f^+) \]

\[ label ::= \text{sequence of chars matching} :[a-zA-Z_][a-zA-Z_0-9]^* \]

\[ f ::= (label \ N \ N \ i^+) \]

\[ i ::= w \leftarrow s \mid w \leftarrow \text{mem } x \ M \mid \text{mem } x \ M \leftarrow s \]
\[ \quad \mid w \text{ aop } t \mid w \text{ sop } rcx \mid w \text{ sop } N \]

\[ \text{sop} ::= \lll \mid \rrr = \]
L1 instruction: memory arithmetic operations

\[ p ::= (\text{label } f^+) \]

\[ \text{label ::= sequence of chars matching } :[a-zA-Z_][a-zA-Z_0-9]^* \]

\[ f ::= (\text{label } N \ N \ i^+) \]

\[ i ::= w < - s | w < - \text{ mem x M} | \text{ mem x M } < - s \]

\[ | w \text{ aop t } | w \text{ sop rcx } | w \text{ sop N} \]

\[ | \text{ mem x M } + = t \]

\[ | \text{ mem x M } - = t \]

\[ | w + = \text{ mem x M} \]

\[ | w - = \text{ mem x M} \]

Notice you cannot have both operands in memory
L1 instruction: comparison

p ::= (label f+)

label ::= sequence of chars matching: [a-zA-Z_][a-zA-Z_0-9] *

f ::= (label N N i+)

i ::= ...
    | w ← t cmp t

cmp ::= < | <= | =

Notice there is neither
> 
nor
>=
L1 example

(:go
  (:go
    4 2
    rax <- 5
    rdi <- rax <= 3
  )
)
)
L1 instruction: comparison

\[ p ::= (\text{label } f^+) \]

\[ \text{label ::= sequence of chars matching } :[a-zA-Z_][a-zA-Z0-9]^* \]

\[ f ::= (\text{label } N N i^+) \]

\[ i ::= ... \]

\[ w \leftarrow t \text{ cmp } t \]

\[ \text{cmp ::= } < | <= | = \]
L1 instruction: conditional jump

\[ p ::= (\text{label } f^+) \]

\[ \text{label} ::= \text{sequence of chars matching } [a-zA-Z_][a-zA-Z0-9]^* \]

\[ f ::= (\text{label } N N i^+) \]

\[ i ::= \ldots \]

\[ | \ w <- t \ \text{cmp } t \]

\[ | \ \text{cjump } t \ \text{cmp } t \ \text{label} \]

\[ \text{cmp} ::= < | <= | = \]

---

Fall-through semantic
L1 example

(:go
  (:go
    4 2
    rax <- 5
    rdi <- rax <= 3
    cjump rdi = 1 :true
  )
)
)
L1 instruction: label and jump

\[ p ::= (\text{label } f^+) \]

\[ \text{label} ::= \text{sequence of chars matching } [a-zA-Z_][a-zA-Z_0-9]^* \]

\[ f ::= (\text{label } N N i^+) \]

\[ i ::= ... \]

\[
| w \leftarrow t \text{ cmp } t \\
| \text{cjum}p t \text{ cmp } t \text{ label} \\
| \text{label} \\
| \text{goto } \text{label}
\]
L1 example

(:go
  (:go
    4 2
    rax <- 5
    rax += 2
    cjump rax <= 3 :END
    rax += 4
    goto :END
    :END
  )
))
L1 instruction: label and jump

p ::= (label f+)

label ::= sequence of chars matching :[a-zA-Z_][a-zA-Z_0-9]*

f ::= (label N N i+)

i ::= ...

  | w <- t cmp t
  | cjump t cmp t label
  | label
  | goto label

The scope of labels is the program
L1 another example

(:F1
  (:F1
    0 0
    :L1
  )
)

(:F2
  0 0
  :L1
)
)
L1 instruction: return

\[ p ::= (\text{label } f^+) \]
\[ \text{label} ::= \text{sequence of chars matching } :[a-zA-Z_][a-zA-Z_0-9]^* \]
\[ f ::= (\text{label } N N i^+) \]
\[ i ::= \ldots \]
  \[ | \text{return} \]
L1 example

(:go
  (:go
    4 2
    rax <- 5
    cjump rax <= 3 :false
    return
    :false
    :false
    :false
    rax += 1
    return
  ))
L1 instruction: call

\[
\begin{align*}
p & := (\text{label } f^+) \\
\text{label} & := \text{sequence of chars matching :}[a-zA-Z_][a-zA-Z_0-9]^* \\
f & := (\text{label } N N \text{ } i^+) \\
i & := \ldots \\
\quad | \text{call } u \text{ } N \\
\quad | \text{call } u \text{ } N \\
\text{Number of arguments of the called function (a.k.a. callee)} \\
u & := w \mid \text{label}
\end{align*}
\]
L1 example

(:go
 (:go
   4 2
   call :myF2 0
   return
 )
 (:myF2
   0 0
   return
 )
 )

Why do we have redundant information in L1?
To simplify the L1 compiler (your work)

They must match

Number of parameters of the function
L1 instruction: call

\[ p ::= (\text{label } f^+) \]
\[ \text{label ::= sequence of chars matching }:[a-zA-Z_][a-zA-Z0-9]^* \]
\[ f ::= (\text{label } N \ N \ i^+) \]
\[ i ::= \ldots \]
\[ \quad | \text{call } u \ N \]
\[ \quad | \text{call } \text{print } 1 \]
L1 example

(:go
 (:go
   4 2
   rdi <- 5
   call print 1
   return
 )
)

The calling convention will be explained soon
L1 instruction: call

\[ p ::= (\text{label } f^+) \]

\[ \text{label ::= sequence of chars matching :}[a-zA-Z_][a-zA-Z_0-9]* \]

\[ f ::= (\text{label } N \ N \ i^+) \]

\[ i ::= \ldots \]

| call u N |
| call print 1 |
| call allocate 2 |
| call allocate-error 2 |
L1 instruction: misc

\[
\begin{align*}
p & ::= (\text{label } f^+) \\
\text{label} & ::= \text{sequence of chars matching } :[a-zA-Z_][a-zA-Z_0-9]^* \\
f & ::= (\text{label } N N i^+) \\
i & ::= ... \\
  & | \ w++ \\
  & | \ w-- \\
  & | \ w \@ \ w \ w \ E \\
\end{align*}
\]

\[
\begin{align*}
\text{rax @ rdi rsi 4} \\
\text{Set rax to rdi + (rsi * 4)} \\
\end{align*}
\]

\[
\begin{align*}
E & ::= 1 \mid 2 \mid 4 \mid 8 \\
\end{align*}
\]
p ::= (label f)

f ::= (label N N i)

i ::= w <- s | w <- mem x M | mem x M <- s |
    w aop t | w sop sx | w sop N | mem x M += t | mem x M -= t | w += mem x M | w -= mem x M |
    w <- t cmp t | cjump t cmp t label | label | goto label |
    return | call u N | call print 1 | call allocate 2 | call array-error 2 |
    w ++ | w -- | w @ w w E

w ::= a | rax | rbx | rbp | r10 | r11 | r12 | r13 | r14 | r15

a ::= rdi | rsi | rdx | sx | r8 | r9

sx ::= rcx

s ::= t | label

t ::= x | N

u ::= w | label

x ::= w | rsp

aop ::= += | -= | *= | &=

sop ::= <<= | >>=

cmp ::= < | <= | =

E ::= 1 | 2 | 4 | 8

M ::= N times 8

N ::= (+|-)? [1-9][0-9]*

label ::= sequence of chars matching :[a-zA-Z_][a-zA-Z_0-9]*
Outline

• Assembler, linker

• L1 language

• Value encoding

• Calling convention

• Heap
<table>
<thead>
<tr>
<th>High level vs. low level languages</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>C language</strong></td>
</tr>
<tr>
<td><code>printf(&quot;5&quot;);</code> You expect the output 5</td>
</tr>
<tr>
<td><strong>Back-end languages</strong></td>
</tr>
<tr>
<td><code>rdi &lt;- 5</code> call print 1` You expect the output ?</td>
</tr>
<tr>
<td>It depends on the encoding scheme designed for correctness</td>
</tr>
</tbody>
</table>
Value encoding in L1

• A value is either an 8 byte integer value or a memory address
• We would like to differentiate between the two
  • Safer programming environment
  • Problem: how to do it?
  • For example:
    mem rdi 8 <- rax
    is the value in rdi a memory address?
• Our solution: using the least significant bit to specify it
  0: it is a memory address
  1: it is an integer value
• Values in L1 are all encoded
High level vs. low level language L1

C language
printf("5"); You expect the output 5

L1 language
rdi <- 5 You expect the output 2
call print 1

00000101 00000010
Decoding an encoded value

• $x \& 1 = 0$
  $x$ is a memory address

• $x \& 1 = 1$
  $x >> 1$ is a 63 bit two’s complement integer

• Values (integer or addresses) must be encoded for runtime APIs
  • print
  • allocate
  • array-error
L1 example

(:go
 (:go
  0 0
  rdi <- 5
  call print 1
  return
 )
)

• print writes to the terminal the integer value encoded in rdi
• What is going to be the output?
  2
Outline

• Assembler, linker
• L1 language
• Value encoding
• Calling convention
• Heap
Calling convention

• How many arguments a given function has?
  call :myF 2

• Where are the arguments stored?

• Who (caller vs. callee) is responsible for what?

• Where is the return value stored?
  rax
The stack in L1

High address

Low address

Stack grows

Bottom

Top
So before calling a function, we need to store the return address on top of the stack.
Storing the return address

Two type of calls:

• Calls to L1 functions
  • L1 code is responsible to store the return address on top of the stack

• Calls to runtime
  • L1 code is not responsible to store the return address on top of the stack
Whoever generates L1 code (developer, compiler that targets L1) is responsible:
• to define the return label just after the call
• to store that label on top of the stack
Function call example (2)

`:myF
  0 0

call print 1

return
```

- The call itself writes the return address on top of the stack
- There is no need to define the label after the call
What about function parameters?

• The convention used in the L1 language is that the first 6 parameters of the callee are passed using registers

• The other parameters are passed using the function frame of the callee stored on the stack
What about the previous value of r10?
• We want to write our function without knowing the registers used/needed by every possible caller
  • Is it possible to know them all?
• Who is responsible to save the previous value?
  • Are we (the callee)?
  • Are the callers?
• We need to establish a convention
Registers

Arguments
- rdi
- rsi
- rdx
- rcx
- r8
- r9

First argument

Result
- rax

Caller save
- r10
- r11
- r8
- r9
- rax
- rcx
- rdi
- rdx
- rsi

Callee save
- r12
- r13
- r14
- r15
- rbp
- rbx
Caller save registers (e.g., r10)

( :myF
  0 1
  r10 <- 5
  mem rsp 0 <- r10
  mem rsp -8 <- :myF2_ret
  call :myF2 0
  :myF2_ret
  r10 <- mem rsp 0
  rdi <- r10
  call print 1
  return
 )

( :myF2
  0 0
  r10 <- 3
  return
 )

What is the output?

Whoever generates L1 code (developer, compiler that targets L1) is responsible to properly save caller-save registers
### Caller save registers (e.g., r10)

Whoever generates L1 code (developer, compiler that targets L1) is responsible to properly save caller-save registers.

R10 is not used after the call. Hence, we don’t need to save it.
Callee save registers (e.g., r12)

Whoever generates L1 code (developer, compiler that targets L1) is responsible to properly save caller-save registers as well as callee-save registers.
Callee save registers (e.g., r12)

Whoever generates L1 code (developer, compiler that targets L1) is responsible to properly save caller-save registers as well as callee-save registers

And now?
The stack in L1

- High address
- Low address
- Ret addr
- Args
- Vars

Bottom to Top
The stack in L1
Stack frame: <= 6 arguments, no locals

(:go
  ...
  mem rsp -8 <- :f_ret
  call :f 1
  :f_ret
    ...
  )
 (:f
  1 0
  return
  )
Stack frame: > 6 arguments, no locals

(:go
  rdi<-1
  rsi<-3
  rdx<-5
  rcx<-7
  r8<-9
  r9<-11
  ...
  call :f 7
  ...
)

Arguments

First argument
Stack frame: > 6 arguments, no locals

(:go
  ... //passing the first 6 arguments
  mem rsp -8 <- :f_ret
  mem rsp -16 <- 11
  call :f 7
  :f_ret
)
(:f
  7 0
  rdi <- mem rsp 0
  call print 1
  return)
Stack frame: <= 6 arguments, 1 local

(:go
   ...
   mem rsp -8 <- :f_ret
   call :f 1
   :f_ret
      ...
   )
(:f
   11
   return
   )
L1 program example

Is there a bug? Where?

What is the output?
Stack frame: > 6 arguments, > 0 locals

(:go
  ... //passing the first 6 arguments
  mem rsp -8 <- :f_ret
  mem rsp -16 <- 11
  call :f 7
  :f_ret
)
(:f
  7 0
  rdi <- mem rsp 0
  call print 1
  return)

What does it print?
Stack pointer

• $\text{rsp}$ (the stack pointer) is never modified directly

• call and return instructions modify $\text{rsp}$ to do their jobs
  (see the grammar)
Outline

• Assembler, linker

• L1 language

• Value encoding

• Calling convention

• Heap
Heap memory in L1

- Arrays are allocated in the heap
- No explicit deallocation
  - A garbage collector is assumed
- APIs
  - allocate:
    allocate an array of a given number of 64-bit integer elements
  - array-error:
    write to stdout an error message and abort the execution
Heap memory in L1

• allocate
  • Argument 1: number of array elements to allocate
  • Argument 2: 64-bit integer value used to initialize all array elements
  • Return: pointer to the array allocated and initialized

• array-error
  • Argument 1: pointer to a previously allocated array
  • Argument 2: number of the element that has been tried to access that does not exist

<table>
<thead>
<tr>
<th>NUMBER OF ELEMENTS</th>
<th>INITIAL VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Not encoded
Example of L1 program using heap memory

```
(:go
 (:go
  0 0
  rdi <- 5
  rsi <- 7
  call allocate 2
  return
 )
)
```
Example of L1 program using heap memory

(:go
  0 0
  rdi <- 5
  rsi <- 7
  call allocate 2
  rdi <- mem rax 8
  call print 1
  return
)

What is the output?

3

rax + 8

\[
\begin{array}{c}
2 \\
7 \\
7 \\
\end{array}
\]
Example of L1 program using heap memory

(:go
  0 0
  rdi <- 5
  rsi <- 7
  call allocate 2
  rdi <- mem rax 16
  call print 1
  return
)

What is the output?

3

rax + 16
Example of L1 program using heap memory

`:go
0 0
rdi <- 5
rsi <- 7
call allocate 2
rdi <- mem rax 0
call print 1
return
)

What is the output?
Segmentation fault

How can we fix this L1 program?
Printing an array

- The API print writes to stdout the whole array if its pointer is passed as argument

```plaintext
rdi <- 5
rsi <- 7
call allocate 2
rdi <- rax
call print 1
{s:2, 3, 3}
```
Array of arrays

(:go 0 0
 rdi <- 5
 rsi <- 7
 call allocate 2
 rdi <- 7
 rsi <- rax
 call allocate 2
 rdi <- rax
 call print 1
 return
)

The output: {s:3, {s:2, 3, 3}, {s:2, 3, 3}, {s:2, 3, 3}}
Final notes

• Every L1 function must return to its caller with a (return) instruction

```plaintext
:wrongF
  0 0
  rax <- 1
)
```

• The calling convention must be preserved always

• You can write comments in L1
  • A comment starts with “//” and it comments until the end of the line
  • Example
    // This is a comment
    rdi <- 5

    // this is another comment
Tests

• Write 3 non trivial (more than 30 instructions) L1 programs
  • The name of the files must end with .L1
  • For example: myTest1.L1
• Deadline: 2 days from today at midnight
• Tests and pairs (just for L1 tests)
  • If you send an email to TA to declare your pair by today at midnight
    • You will need to upload 3 tests per pair
  • Otherwise
    • You will need to upload 3 tests yourself
